    int max = arr[0];
    for(int i=1; i<size; i++) {
        if(arr[i] > max) {
            max = arr[i];
        }
    }
    return max;
}
int main() {

}

```

Linked Lists Linked lists are dynamic data structures where elements (nodes) are linked using pointers, allowing efficient insertion and deletion.

Types: Singly, doubly, and circular linked lists.

#include <stdlib.h>
struct Node {
    int data;
    struct Node next;
};
void insertAtBeginning(struct Node head_ref, int new_data) {
    struct Node new_node = (struct Node) malloc(sizeof(struct Node));
    new_node->data = new_data;
    new_node->next = (head_ref);
    (head_ref) = new_node;
}
void printList(struct Node node) {
    while (node != NULL) {
        printf("%d -> ", node->data);
        node = node->next;
    }
    printf("NULL\n");
}

    struct Node head = NULL;
    insertAtBeginning(&head, 10);
    insertAtBeginning(&head, 20);
    insertAtBeginning(&head, 30);
    printList(head);

}

```

Stacks and Queues Stacks and queues are linear data structures with specific access patterns.

Stack: Last-In-First-Out (LIFO)

int stack[MAX];
int top = -1;
void push(int item) {
    if(top == MAX - 1) {
        printf("Stack overflow\n");
    } else {
        stack[++top] = item;
    }
}
int pop() {
    if(top == -1) {
        printf("Stack underflow\n");
        return -1;
    } else {

Advanced Data

Structures in C Building upon basic structures, advanced data structures enhance performance for complex operations.

Hash Tables Hash tables provide fast data retrieval using key-value pairs. Implementation: Using arrays of linked lists (chaining) or open addressing. Use Case: Implementing dictionaries, caches.

Binary Trees and Binary Search Trees (BST) Trees organize data hierarchically, enabling efficient searches. BST: Left child contains smaller, right child contains larger data. Operations: Insert, delete, search. Example: BST Search in C

```

#include <stdio.h>
#include <stdlib.h>
struct Node {int data; struct Node left; struct Node right;};
struct Node createNode(int data) {struct Node newNode = malloc(sizeof(struct Node)); newNode->data = data; newNode->left = NULL; newNode->right = NULL; return newNode;}
struct Node insert(struct Node root, int data) {if(root == NULL) return createNode(data); if(data < root->data) root->left = insert(root->left, data); else if(data > root->data) root->right = insert(root->right, data); return root;}
int search(struct Node root, int key) {if(root == NULL) return 0; if(root->data == key) return 1; else if(key < root->data) return search(root->left, key); else return search(root->right, key);}
int main() {struct Node root = NULL; root = insert(root, 50); insert(root, 30); insert(root, 70); printf("Searching for 30: %s\n", search(root, 30) ? "Found" : "Not Found"); return 0;}

```

Introduction to Data Structures in C C, being a low-level procedural

programming language, provides programmers with the tools necessary to implement a wide variety of data structures. Unlike high-level languages that often come with built-in data structures (like lists or dictionaries), C requires developers to explicitly define and manage these structures, offering both power and responsibility. Understanding data structures in C is not just academic; it directly impacts the efficiency of algorithms, memory management, and overall program performance. Mastery of data structures enables developers to optimize code for speed and resource utilization, which is crucial in systems programming, embedded systems, and performance-critical applications.

Core Data Structures in C: An In-Depth Overview

The primary data structures in C can be categorized into linear and nonlinear structures. Each serves specific purposes and has unique implementation considerations.

Linear Data Structures

Linear data structures organize data in a sequential manner, where elements are stored one after another.

Arrays

Overview: Arrays are contiguous blocks of memory that store elements of the same data type. They are the simplest form of data storage in C, offering direct access via indices.

Implementation Highlights:

- Declaring an array:** `int arr[10];`
- Accessing elements:** `arr[0]`, `arr[1]`, etc.
- Fixed size:** Arrays have a predefined size at compile time, which can be a limitation.
- Advantages:** Constant-time access ($O(1)$) for elements via index. Efficient memory utilization when size is known beforehand.
- Limitations:** Fixed size; resizing requires creating a new array and copying data. Insertion and deletion (except at the end) are costly, requiring shifting elements ($O(n)$).
- Best Use Cases:** Static datasets with known size. Situations requiring fast random access.

Linked Lists

Overview: A linked list is a dynamic data structure consisting of nodes where each node contains data and a pointer to the next node.

Implementation Highlights:

- Defining a node:** `struct Node {int data; struct Node next;};`
- Creating and linking nodes dynamically using `malloc()`:**
- Advantages:** Dynamic size; easy insertion/deletion at any position ($O(1)$ if pointer to node is known). Memory efficient for unpredictable data sizes.
- Limitations:** Sequential access; traversal is necessary ($O(n)$ access time). Extra memory overhead for pointers.
- Best Use Cases:** When frequent insertions/deletions are needed. Managing dynamic datasets where size varies over time.

Non-Linear Data Structures

Non-linear structures organize data hierarchically or in complex relationships.

Stacks

Overview: A stack follows the Last-In-First-Out (LIFO) principle. It is an abstract data type where insertion and deletion happen at one end.

Implementation Highlights:

- Using arrays or linked lists:** `#define MAX 100 int stack[MAX]; int top = -1;`
- Push operation:** `void push(int x) {if (top < MAX - 1) {stack[++top] = x;}}`
- Pop operation:** `int pop() {if (top >= 0) {return stack[top--];} return -1; // Underflow}`
- Advantages:** Simple and efficient for backtracking, expression evaluation, etc. Constant-time $O(1)$ for push and pop.
- Limitations:** Fixed size when implemented with arrays. Limited access? only top element is accessible.
- Best Use Cases:** Expression parsing, backtracking algorithms, undo operations.

Queues

Overview: Queues follow the First-In-First-Out (FIFO) principle. Elements are added at the rear and removed from the front.

Implementation Highlights:

- Using arrays or linked lists:** `int queue[MAX]; int front = 0, rear = -1;`
- Enqueue:** `void enqueue(int x) {if (rear < MAX - 1) {queue[++rear] = x;}}`
- Dequeue:** `int dequeue() {if (front <= rear) {return queue[front++];} return -1; // Underflow}`
- Advantages:** Suitable for scheduling, buffering, and breadth-first search (BFS). Efficient in maintaining order.
- Limitations:** Fixed size unless dynamically resized. Deletion at front involves shifting in array-based implementations unless circular queue is used.
- Best Use**

Cases: Scheduling tasks, message queues, BFS traversal. Trees Overview: Trees are hierarchical structures with nodes connected by edges, most notably binary trees, binary search trees (BST), heaps, and AVL trees. Implementation Highlights: Each node contains data and pointers to child nodes: ``cstruct TreeNode {int data; struct TreeNode left; struct TreeNode right;}`` Recursive functions for traversal: In-order Pre-order Post-order Advantages: Efficient search, insert, delete operations in BSTs ($O(\log n)$ in balanced trees). Hierarchical data representation. Limitations: Complex implementation, especially for self-balancing trees. Overhead in maintaining tree properties. Best Use Cases: Database indexing, file systems, priority queues. Implementing Data Structures in C: Best Practices and Solutions Implementing data structures in C requires a disciplined approach, emphasizing memory management, modularity, and robustness. Memory Management Use `malloc()`, `calloc()`, and `free()` wisely to allocate and deallocate memory. Always check the return value of memory allocation functions to prevent segmentation faults. Avoid memory leaks by ensuring every `malloc()` has a corresponding `free()`. Modularity and Reusability Encapsulate data structure operations within functions. Use `typedef` to define clear and concise type aliases. Modularize code into header files (`.h`) and implementation files (`.c`) for clarity and reuse. Error Handling and Edge Cases Handle overflow and underflow conditions explicitly. Validate pointers before dereferencing. Implement comprehensive test cases covering edge cases like empty structures, full capacity, and invalid operations. Practical Examples and Solutions Let's consider some real-world C solutions exemplifying the implementation of key data structures with best practices. Array Implementation: Dynamic Resizing ``cinclude include typedef struct {int data; int size; int capacity;} DynamicArray; void initArray(DynamicArray arr, int capacity) {arr->data = malloc(capacity * sizeof(int)); arr->size = 0; arr->capacity = capacity;} void resizeArray(DynamicArray arr) {arr->capacity = 2 * arr->capacity; arr->data = realloc(arr->data, arr->capacity * sizeof(int));} void insert(DynamicArray arr, int value) {if (arr->size == arr->capacity) {resizeArray(arr);} arr->data[arr->size++] = value;} void freeArray(DynamicArray arr) {free(arr->data); arr->data = NULL; arr->size = 0; arr->capacity = 0;} int main() {DynamicArray arr; initArray(&arr, 4); insert(&arr, 10); insert(&arr, 20); insert(&arr, 30); insert(&arr, 40); insert(&arr, 50); // Triggers resize for (int i = 0; i < arr.size; i++) {printf("%d ", arr.data[i]);} freeArray(&arr); return 0;}`` This code exemplifies a dynamic array with resizing capabilities, aligning with modern C best practices for flexible data storage. Linked List: Insert and Delete Operations ``cinclude include struct Node {int data; struct Node next;}; void insertAtBeginning(struct Node head_ref, int new_data) {struct Node new_node = malloc(sizeof(struct Node)); new_node->data = new_data; new_node->next = head_ref; head_ref = new_node;} void deleteNode(struct Node head
